

NeoMundi — Executive Brief 2026

NeoMundi measures. Your systems decide.

A runtime measurement layer designed to produce observable governance signals without requiring access to generated content.

Your AI keeps the voice. Your systems keep the decision. Your auditors keep the trace.

The Problem

AI responds. You assume liability.

An unobserved drift. An atypical regime passing under the radar. An audit trace missing the day it becomes necessary.

Today, in most AI deployments, what happens during or around generation remains poorly instrumented from a runtime governance perspective.

You know a response was produced. You do not always know under which behavioral conditions it was generated, nor whether you will be able to demonstrate it months later.

Every undocumented generation becomes a governance risk that is difficult to verify retrospectively.

What NeoMundi Does

NeoMundi is a runtime measurement layer.

Not a guardrail. Not a truth arbiter. Not a full cognition reconstruction system.

Integrated into your generation pipeline, NeoMundi produces runtime governance signals and artifacts that your systems can observe, classify, route, or use inside their own governance workflows.

NeoMundi does not decide for you. NeoMundi measures and signals. Your governance logic remains under your control.

One API call. One runtime measurement. Your systems decide.

The Core Product Mode: OBS

OBS is the governance observability mode without content transmission.

Your application calls your model directly. NeoMundi only receives observable runtime metrics and signals associated with execution.

Never the prompt. Never the response.

Depending on configuration and available artifacts, NeoMundi may produce:

- a normalized governance stability state,
- a runtime regime classification,
- a governance decision (PASS / FLAG),
- timestamped audit-ready artifacts,
- runtime telemetry signals associated with execution.

Why OBS Matters

Compatibility with Sensitive Environments

OBS operates on systems where content cannot be shared:

- healthcare,
- legal,
- defense,
- personal data,
- sovereign environments.

NeoMundi does not receive generated content. The content remains within your perimeter.

Lightweight Integration

OBS integrates above an existing stack without modifying the generation pipeline.

Governance Independent from the Model

OBS produces governance artifacts independent from the model itself and from any self-evaluation mechanism.

No Critical Latency Impact

OBS does not introduce significant latency into the critical client response path.

OBS is available in production.

The Complementary Mode: GOV

When clients require runtime orchestration during generation, NeoMundi provides GOV mode.

In GOV mode, NeoMundi sits between your application and the LLM provider.

NeoMundi calls the model on your behalf while simultaneously producing:

- the generation stream,
- runtime signals,
- associated governance artifacts.

Content transits. It is neither retained nor logged.

GOV is intended for situations where an incorrect output reaching a user becomes non-recoverable.

Examples include:

- medical advice,
- directly delivered legal advice,
- fiduciary financial decisions,
- critical infrastructure,
- systems subject to reinforced supervision.

GOV is available in production.

Two Deployment Modes

ControlTower™ acts as a control tower for generative AI governance.

Continuous observability in OBS. Runtime orchestration in GOV when intervention becomes critical.

	OBS	GOV
Purpose	Governance observability	Runtime governance orchestration
Timing	Post-execution / continuous observability	During generation
Privacy	No content transmitted	Transient runtime flow, without logging or retention
Integration	The LLM calls NeoMundi	NeoMundi calls the LLM
Best suited for	Most AI systems	Critical workflows

Decision Criterion

If a bad output reaches the user, is it recoverable?

Recoverable

- alerting,
- downstream moderation,
- next-cycle correction,

- human review.

OBS is generally sufficient.

Non-Recoverable

- medical advice,
- fiduciary decisions,
- critical infrastructure,
- highly regulated supervision.

GOV becomes necessary.

Where NeoMundi Creates Value

AI Agents in Production

Runtime signals usable to:

- reroute,
- escalate,
- regenerate,
- supervise,
- or observe behavioral drift.

Compliance and Audit

Production of timestamped governance artifacts usable inside:

- compliance workflows,
- audit systems,
- governance pipelines,
- runtime supervision environments.

Fine-Tuning and Model Selection

Observation of behavioral variations between:

- model versions,
- providers,
- configurations,
- datasets.

Infrastructure and SLA

Continuous behavioral observability designed to document:

- service quality,
- operational stability,
- runtime supervision,
- execution continuity.

NeoMundi measures. Your systems decide. Your auditors keep the trace.

Validation

Current evaluations have been conducted primarily in GOV mode under controlled runtime configurations.

Cartography v1 — April 2026

- 5 LLM providers tested,
- 3,904 generations analyzed (TruthfulQA),
- observed precision: 75.7%,
- observed recall: 15.2%.

The instrument remains conservatively calibrated.

Precision is prioritized in order to reduce false positives and preserve governance workflows.

Observed signatures remain consistent from one run to another within the configurations currently tested.

Protocols, scripts, and results are published reproducibly through:

- Zenodo (DOI 10.5281/zenodo.19762753)
- GitHub

Public definitions of the G and ΔG runtime telemetry signals, together with their associated methodological boundaries, are documented in the public Runtime Telemetry Signals repository: <https://github.com/neomundi-io/runtime-telemetry-signals>

EU AI Act

Traceability, supervision, and governance requirements for high-risk AI systems become central under the EU AI Act beginning August 2, 2026.

NeoMundi does not provide regulatory certification.

NeoMundi provides a complementary runtime governance layer capable of producing:

- timestamped governance artifacts,
- supervision signals,
- observability traces,
- and audit-ready runtime reporting elements.

These artifacts may contribute to supervision and traceability requirements introduced by the European regulatory framework.

Positioning

Portkey transports. LangSmith analyzes. Helicone logs.

These tools primarily operate on:

- workflows,
- application metadata,
- cost,
- latency,
- or content.

NeoMundi adds a complementary runtime governance and behavioral telemetry layer.

Category:

Governance-oriented runtime measurement layer.

Not a firewall. Not a guardrail. Not a semantic truth system.

A signal infrastructure upon which your systems can base their decisions.

Use Case — Legal Firm

A law firm uses a general-purpose AI assistant to prepare client-facing legal summaries.

The legal content handled by the assistant is protected by professional secrecy and cannot be transmitted to an external monitoring provider.

With NeoMundi in OBS mode:

- prompts and responses remain inside the firm's perimeter,
- only runtime metrics and governance artifacts are transmitted,
- NeoMundi produces a governance stability state and a timestamped trace for each generation.

When a generation exhibits an atypical regime:

- the signal degrades,
- the regime classification changes,
- the decision switches to FLAG,
- the firm's workflow automatically routes the output to a senior lawyer before client delivery.

Legal liability is not eliminated.

It becomes observable, measurable, and documentable.

The trace exists before an audit requires it.

In Summary

Behavioral stability is no longer merely assumed.

It becomes observable through runtime signals and governance artifacts usable by your systems.

NeoMundi measures. Your systems decide.

Plug in NeoMundi. First signal in minutes.
