

NeoMundi - Executive Brief 2026

NeoMundi measures. You decide.

A runtime measurement layer capable of operating without access to generated content. Your AI keeps the voice. Your systems keep the decision. Your auditors get the trace.

The problem

The AI responds. You take responsibility.

An unmeasured drift. An atypical regime that slipped under the radar. An audit trace that is not there the day someone asks for it.

In most deployments today, what happens during a generation is not instrumented. You know a response was produced. You do not know in which stability regime it was produced, nor whether you will be able to demonstrate it six months later.

Every unmeasured response is an undocumented decision.

What NeoMundi does

NeoMundi is a measurement layer. Not a guardrail. Not a detector. Not a judge.

Connected to your generation pipeline, it produces a runtime signal that your systems can observe, classify, route, or use as a basis for governance. NeoMundi does not decide for you. It measures and signals. Your governance logic stays under your control.

One API call. A runtime measurement. Your systems decide.

The flagship mode: OBS

OBS is the measurement mode without access to content.

Your application calls your model directly. NeoMundi only receives execution metrics: token volume, latency, model identifier. Never the prompt. Never the response.

From these metrics, NeoMundi produces:

- a stability score (between 0 and 1)
- a regime classification: STABLE, SIGNAL, CRITICAL
- a decision: ALLOW or FLAG
- a timestamped trace, suitable for audit workflows

Why OBS is central to our offering:

- It operates on content you are not allowed to share. Healthcare, legal, defense, personal data, sovereign contexts. NeoMundi does not see the content, so the content does not leave your perimeter.
- It integrates on top of an existing stack without modifying the generation chain.
- It produces an audit trace independent of the model, neither generated by it, nor biased by its own self-evaluation.
- It introduces no latency on the critical path of the client response.

OBS is available in production.

The complementary mode: GOV

When the client wants inline measurement during generation rather than after the fact, NeoMundi provides a GOV mode.

In this mode, NeoMundi sits between your application and the LLM provider. It calls the model on your behalf and streams the response and the signal back to your system. Content is in transit. It is never retained.

GOV is available in production.

Where NeoMundi creates value

AI agents in production

Runtime stability signal usable by your systems to reroute, escalate, regenerate, or supervise atypical generations.

Compliance and audit

Production of a timestamped trace independent of the model, suitable for use in your compliance, audit, and governance workflows.

Fine-tuning and model selection

Measurable comparison of stability regimes across versions, providers, or datasets.

Infrastructure and SLA

Continuous measurement of generation behavior to document service quality, continuity, and operational stability.

NeoMundi measures. Your systems decide. Your auditors see.

Validation

NeoMundi publishes the calibration of its instrument on 3,904 TruthfulQA measurements, a reference benchmark for factual coherence evaluation.

Global performance, cartography v1, April 2026:

- **Precision: 75.7%**
- **Recall: 15.2%**

The instrument is calibrated conservatively. Precision is privileged over coverage to limit false positives and preserve the quality of governance workflows.

Per-provider performance, on the same protocol and the same data, is detailed in the public cartography. The stability signatures observed remain consistent from one run to the next.

Cartography versioned and publicly hosted: Zenodo (DOI 10.5281/zenodo.19762753) and GitHub. Protocols, scripts, and results reproducible by any third party.

EU AI Act

Requirements for traceability, supervision, and governance of high-risk AI systems become central in the EU AI Act framework starting August 2, 2026. The European regulatory framework provides for significant penalties in cases of non-compliance.

NeoMundi does not provide compliance certification. No tool alone can. NeoMundi provides the missing layer that most current deployments do not produce today: a timestamped stability trace, independent of the model, directly usable by your internal compliance process or by an external auditor.

Positioning

Portkey transports. LangSmith analyzes. Helicone logs. All these tools operate on content and on cost or latency metadata, before or after generation.

NeoMundi operates on the stability signature of the generation itself, without necessarily seeing the content.

Category: runtime measurement layer, content-independent.

Not a firewall. Not a guardrail. Not a hallucination detector. A signal infrastructure on which your systems base their decisions.

Use case: law firm

A law firm uses a generalist AI assistant to prepare briefing notes for its clients. The legal content handled is covered by attorney-client privilege and cannot be shared in the clear with a third-party monitoring provider.

With NeoMundi in OBS mode, the firm keeps its prompts and responses within its own perimeter. Only execution metrics are transmitted. NeoMundi produces a stability score and a timestamped trace for each generation.

When an assistant produces a response whose generation regime departs from the observed norm, the score falls, the classification shifts to SIGNAL or CRITICAL, the decision moves to FLAG, and the firm's system routes the response to a senior lawyer for review before transmission to the client.

Legal liability is not eliminated. It becomes measurable and documentable. The trace exists before an audit demands it.

In summary

The stability of generations is no longer assumed. It is measured continuously.

NeoMundi measures. You decide.

Plug in NeoMundi. First signal in a few minutes.
